Factors Influencing Background Incidence Rate Calculation: Systematic Empirical Evaluation Across an International Network of Observational Databases. *Frontiers in Pharmacology*; 2022

# Drug (vaccine) safety studies

Observed rate of adverse event

FDA's Adverse Event Reporting System  
Adverse events following exposure in  
EHR and claims data

vs

Expected rate of adverse event

Background (baseline, historic) rates of  
adverse events in EHR and claims data

# Background incidence rates

New cases

Time at risk (TAR)

Background  
incidence rate

=

New cases during specified time period

---

Person-time of the at-risk population

Population

Estimates of baseline incidence of *stroke* in different studies: **4.6 – 679** per 100,000 person-years depending on the population, time-at-risk, data source.

# Systematic experiment

12 data sources

**15** adverse events  
(Brighton list)  
**2** new case  
identification  
strategies

2017-2020  
**8** age groups  
**3** condition groups  
**2** sexes  
**2** races

**4** index dates  
**2** TAR starts  
**5** TAR durations  
**4** years  
**4** seasons

**10** research questions, compute **incidence rates** and incidence rate **ratios**, random effect model **meta-analysis**

# Main findings

## Magnitude of influence

Age

E.g., pooled incidence rates of acute myocardial infarction in 6-17 yo is <1 per 100,000 PY and ~1,330 per 100,000 in 85+ yo group

Data source

Index date (anchoring)

\* Date vs visit

Condition subgroups\*

\* Patients with chronic conditions

Gender

Race

Season\*

New case identification strategy (clean window)

\* Season and comparison of COVID-19 pandemic versus previous years

# Selecting an **index date** in a cohort or case-crossover study

Exposed group/time

Drug exposure date  
Vaccination date  
Procedure date

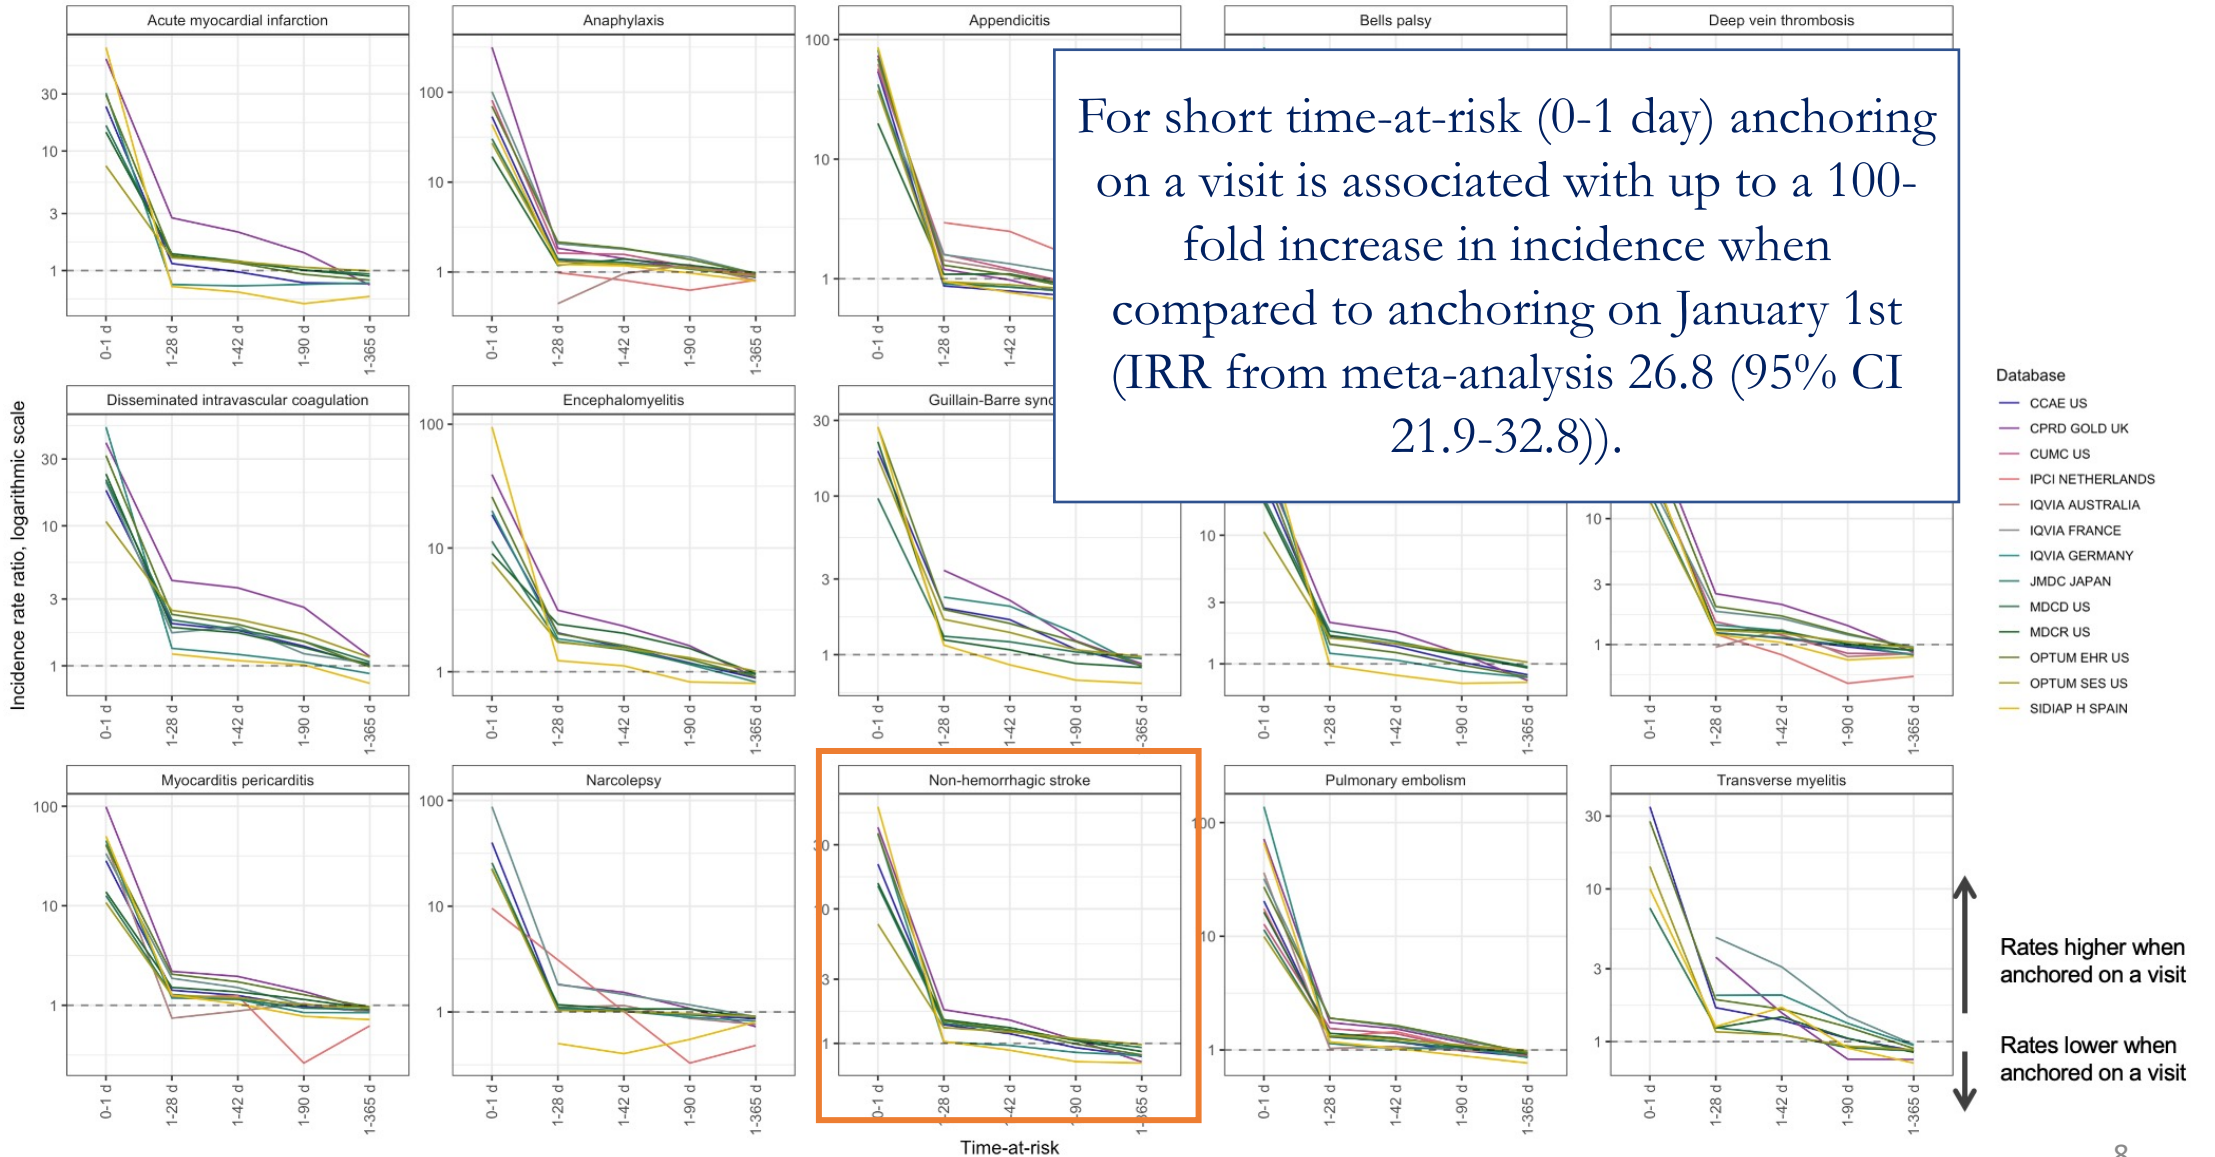

Unexposed group/time

January 1<sup>st</sup>?  
A random date?  
A visit?  
Something else?

# Anchoring on a visit increases incidence rates for short and medium time-at-risk intervals for all conditions

Comparison of anchoring on a random visit versus anchoring on January 1<sup>st</sup> in patients with a visit in the next year, incidence rate ratio.

# Main findings

## Magnitude of influence

Age

E.g., pooled incidence rates of acute myocardial infarction in 6-17 yo is <1 per 100,000 PY and ~1,330 per 100,000 in 85+ yo group

Data source

Index date (anchoring)

\* Date vs visit

Condition subgroups\*

\* Patients with chronic conditions

Gender

Race

Season\*

New case identification strategy (clean window)

\* Season and comparison of COVID-19 pandemic versus previous years

# Key findings

- Age has the largest impact on incidence with incidence rates varying up to a factor of 1,000 across age groups.
- Anchoring has a great impact on incidence rates (and patient characteristics). Anchoring time-at-risk interval on any type of healthcare encounter yielded higher incidence when compared to anchoring on a random date, especially for the short time-at-risk.
- Temporal and seasonal trends, gender, race and clean window choice have moderate influence

# Key implications

- As population characteristics have high impact on baseline rates, population used for background rates calculation should represent the population for observed rate calculations
- As background rates don't have a definitive point-in-time index date for time-at-risk interval, we must select an index date or event (anchor) that serves as a counterfactual for exposure (vaccination) based on the background knowledge and empirical assessment
