Development of psychiatric common data model (P-CDM) leveraging psychiatric scales
Dong Yun Lee, Chungsoo Kim, Rae Woong Park

Background
The limitations of a categorical diagnostic system in neuropsychiatric illness have become increasingly apparent. A diagnostic category such as depression captures a large heterogeneous range of presentations.\(^1\) By categorizing various symptoms with only a diagnosis code, there is a loss of information.\(^2\) To compensate for these issues, various psychiatric scales have been introduced and are used in practice.\(^3\) However, the common data model does not include psychiatric scales. Therefore, we aimed to develop a common data model for psychiatry that utilizes the psychiatric scale.

Methods
First, we built the psychiatric CDM from the existing CDM of Ajou University School of Medicine (AUSOM). Specifically, the psychiatric CDM was created by extracting CDM records for patients with at least one visit to a psychiatry department since 2010. While extracting patients, we kept the existing CDM table and format. For the psychiatric scales, information was extracted from the EHR and loaded into the psychiatric CDM. We decided to extract common scales by asking four psychiatrists what scales they commonly use. Second, the extracted scales were mapped to SNOMED-CT concepts and loaded into the measurement table of the psychiatric CDM.

Results
The psychiatric CDM included 32,553 patients, 42.8% male and 57.2% female. The most common diagnosis was adjustment disorder, followed by sleep disorder, depressive disorder, and panic disorder. There were a total of 8 psychiatric scales selected for extraction (Hamilton Rating Scale for Depression (HAM-D), Hamilton Rating Scale for Anxiety (HAM-A), Beck Depression Inventory (BDI), Beck Anxiety Inventory (BAI), Brief Psychiatric Rating Scale (BPRS), Positive and Negative Syndrome Scale (PANSS), MMSE, and Clinical Dementia Rating Scale (CDR)). The scales were mostly mapped to SNOMED-CT codes, with HAM-A mapped to omop-extension. After ETL, MMSE had the highest number of persons at 1,670, followed by HAM-D at 1,479. The other scales were HAM-A at 745, BDI at 562, BAI at 152, BPRS at 774, PANSS at 260, and CDR at 1,259.

Conclusion
We developed psychiatric CDM leveraging psychiatric scales, which may help capture psychiatric patients more accurately and facilitate their utilization.
